## Model of substance EauSalee

The external substance is used to model a salt water solution with the boiling point elevation given in the following figure.

The calculation principle is to consider that the properties of the solution are those of water at a temperature offset from the elevation value, itself modeled as a quadratic function of the solute concentration.

 Please refer to Java code of the external class for more details.

For an alternative model with a different elevation, simply subclass EauSalee changing methods getType() et getDelay().
